In particular, while laser annealing using pulse-mode irradiation is expected to become the mainstream from a viewpoint of cost, in a structure having a silicon semiconductor layer on an insulator substrate, since an irradiation region is limited to a localized region in a surface of a glass substrate, excellent crystallinity of silicon in a microregion cannot be sufficiently obtained. Further, in a case of shortening a pulse width, it is difficult to obtain crystallinity in a microregion. Consequently, in a thin film transistor with a channel length of equal to or shorter than 2 μm, sufficient drain current and the like cannot be obtained. On the other hand, in a case of laser annealing in which a wide area is irradiated in a pulse mode with a large number of pulses, although the problem of crystallinity in a microregion is solved, since a laser beam can be easily spread, there are problems that the size of the beam is large and the energy efficiency is low. Accordingly, in view of cost and energy efficiency, 09e8f5149f
